Dear Somesh Rahul,

You are invited to review paper #107 in 5th IEEE International Conference of Power, Control and Computing Technologies ICPC2T 2026 by Chair.

Title:

Enhanced Classification of Kidney Abnormalities Using CNN-XGBoost Hybrid Framework

Abstract:

Kidney diseases, including cysts, stones, tumors, and normal conditions, significantly impact global health. Early and accurate detection is crucial for effective treatment. Computed Tomography (CT) provides detailed anatomical images, but manual interpretation is time-consuming and prone to variability. This study proposes a hybrid deep learning model combining Convolutional Neural Networks (CNNs) for feature extraction and Extreme Gradient Boosting (XGBoost) for classification. CNNs capture spatial and structural features, while XGBoost robustly handles class imbalance and nonlinear patterns. Evaluated on kidney CT images, the hybrid model achieved 97% accuracy, outperforming standalone CNN or XGBoost, highlighting its potential for clinical decision support.

Dear Somesh Rahul,

You are invited to review paper #112 in 5th IEEE International Conference of Power, Control and Computing Technologies ICPC2T 2026 by Chair.

Title:

A Smart NDVI and Classification-Based System for Monthly Forest Change Detection and Alert Notifications

Abstract:

Deforestation is one of the major issues that threatening ecosystems in worldwide. It causing the biodiversity loss, climate imbalance, and soil degradation. For this Traditional monitoring methods are manual, time-consuming, and lack in real-time accuracy. The forest departments struggled to take quick action and felt difficult to maintain the ecosystem . To overcome these struggles, we proposes a detection system that to analyse and identify the forest loss in specified range of forest. Sentinel-2 satellite image is used to discover the deforestation by applying the Normalized Difference Vegetation Index (NDVI) and Change Detection algorithms, which are widely used to measure vegetation health and detect variations in forest cover. By comparing old and new satellite images on a monthly basis, the system predicts changes in vegetation and calculates key indicators such as NDVI %, Change %, and Tree Loss %. The results are then delivered through a role-based platform, where administrators can manage analyses and generate reports, while forest officers receive timely alerts whenever NDVI predicts forest's critical condition. This approach ensures accurate, software-based, and efficient monitoring, solving the struggles of manual surveys by enabling faster detection, reliable reporting, and proactive forest conservation measures.
